

$$\frac{dW_i}{dt} = - \sum_j Q_{ij} [R_i(W_i; \Theta_i), R_j(W_j; \Theta_j); \Theta_{ij}] + \sum_k U_{ik} [R_i(W_i)]$$

One balance equation per block. The solver assembles them into a system of nonlinear ODEs and integrates it with an implicit Newton–Raphson scheme and an adaptive time step. Nothing in the engine is specific to water.
